# Further Remarks on the Impossibility of a Scalar-Meson "Bootstrap"* 

P. D. B. Collins<br>Lawrence Radiation Laboratory, University of California, Berkeley, California

(Received 18 March 1965)

#### Abstract

Some lacunae in our previous argument that a single particle can not form a self-sustaining or "bootstrap" system are filled. We propose a method of treating the "potential" that reconciles the Mandelstam iteration procedure with the Regge asymptotic behavior of the double spectral function, by making a subtraction of the $S$-wave discontinuity. This leads to a more general argument that unitarity and crossing symmetry put a very stringent limit on the magnitude of the coupling strength, and exclude the possibility of even producing the bound state corresponding to the particle.

## I. INTRODUCTION

IN a recent paper ${ }^{1}$ we attempted to demonstrate that it was impossible for a scalar meson to "bootstrap" itself. We showed that there was no solution to the $N / D$ equations for a crossing-symmetric $S$ matrix which had the required bound-state pole corresponding to the meson. The residue of the direct-channel pole produced in the solution $g$ was much greater than the residues of the crossed-channel poles $g^{\prime}$ which were needed to produce a bound state of the correct energy. But our result depended upon three assumptions which we now wish to examine more closely.

The first was the dominance of nearby singularities, of which we used only the crossed-channel poles and the $S$-wave part of the two-particle elastic unitary cut. Because of the very large coupling constant which was needed, there is some doubt as to the validity of this assumption, especially in view of results obtained in a similar nonrelativistic potential problem, where comparison with the exact solution is possible. We refer to the careful analysis of the $N / D$ method by Luming. ${ }^{2}$ We have thus been led to try to obtain a better understanding of the limitations to our approximation to the "potential."

The second assumption was that one could neglect the fact that the input poles should be continuable in angular momentum, and could use a potential function corresponding to the exchange of an elementary particle. This would not be a good approximation if the trajectory on which the particle lay continued to high values of the angular momentum, producing perhaps a second particle of $\operatorname{spin} 2$. There was also the possibility that there might be a Pomeranchuk trajectory, with the meson lying on a secondary trajectory. This would correspond more closely to the real world, where cross sections tend to constants at high energies. Though we have not been able to use "Reggeized" potentials, we have examined the output trajectories, and find that neither of these possibilities seems to bring us nearer to a "bootstrap" solution.

[^0]We do, however, take note of the conflict between the Mandelstam iteration procedure for obtaining the elastic double-spectral functions, and the requirements of Regge asymptotic behavior. We demonstrate a method for resolving the conflict in practical calculations by explicitly subtracting the $S$-wave discontinuity.

Finally, in the last section we show that unitarity and crossing symmetry put a general constraint on the coupling constants, which is stringent enough to exclude the values that were necessary to produce the meson bound state. We thus have a new reason for rejecting the possibility of a "bootstrap" solution.

## II. FIRST BORN APPROXIMATION

Because we wish to examine complete trajectories, we remove the threshold behavior and instead of the partial-wave amplitude $A_{l}(s)$ consider the function $B_{l}(s)=q_{s}{ }^{-2 l} A_{l}(s)$. This is necessary because the $N / D$ method will not guarantee the correct threshold behavior for $A_{l}$ unless, "per impossibile," we know the complete left-hand cut. In the usual way we set

$$
\begin{equation*}
B_{l}(s)=N_{l}(s) / D_{l}(s), \tag{2.1}
\end{equation*}
$$

where $N_{l}(s)$ has the left-hand and $D_{l}(s)$ the right-hand cuts of $B_{l}(s)$, and we take $B_{l}(s)$ to have the same lefthand singularities as the potential function $V_{l}(s)$ to be derived subsequently.

Thus in dispersion form we have

$$
\begin{equation*}
N_{l}(s)=V_{l}(s) D_{l}(s)-\frac{1}{\pi} \int_{s_{0}}^{\infty} \frac{\operatorname{Im}\left\{D_{l}\left(s^{\prime}\right) V_{l}\left(s^{\prime}\right)\right\}}{s^{\prime}-s} d s^{\prime} \tag{2.2}
\end{equation*}
$$

and

$$
\begin{equation*}
D_{l}(s)=1+\frac{1}{\pi} \int_{s_{0}}^{\infty} \frac{\operatorname{Im}\left\{D_{l}\left(s^{\prime}\right)\right\}}{s^{\prime}-s} d s^{\prime} \tag{2.3}
\end{equation*}
$$

where $s_{0}=4 m^{2}$ is the elastic threshold.
The unitarity relation is

$$
\begin{equation*}
\operatorname{Im}\left\{D_{l}(s)\right\}=-\rho_{l}(s) N_{l}(s), \tag{2.4}
\end{equation*}
$$

where the phase-space factor is

$$
\rho_{l}(s)=[(s-4) / s]^{1 / 2}[(s-4) / 4]^{l}
$$

with relativistic kinematics, or $\rho_{l}(s)=\left[\frac{1}{4}(s-4)\right]^{l+1 / 2}$ with nonrelativistic kinematics.

Combining (2.2), (2.3), and (2.4), we obtain

$$
\begin{align*}
& V_{l}(s)=V_{l}(s)+\frac{1}{\pi} \int_{s_{0}}^{\infty} d s^{\prime} \frac{V_{l}\left(s^{\prime}\right)-V_{l}(s)}{s^{\prime}-s} \rho_{l}\left(s^{\prime}\right) N_{i}\left(s^{\prime}\right)  \tag{2.5}\\
& D_{l}(s)=1-\frac{1}{\pi} \int_{s_{0}}^{\infty} d s^{\prime} \frac{\rho_{l}\left(s^{\prime}\right) N_{l}\left(s^{\prime}\right)}{s^{\prime}-s} \tag{2.6}
\end{align*}
$$

This form of the $N / D$ equations has been preferred to that used in I. The equations have been programmed for the computer by Teplitz and Teplitz, ${ }^{3}$ and in the following calculations we have used a modified form of their program.

If we consider the force from the exchange of a spinzero particle in both the $t$ and $u$ channels we have

$$
\begin{align*}
V_{l}(s)= & \frac{1}{2 q_{s}^{2 l}} \int_{-1}^{1} d(\cos \theta) P_{l}(\cos \theta) \\
& \times\left\{\frac{g}{m^{2}+2 q_{s}^{2}(1+\cos \theta)}+\frac{g}{m^{2}+2 q_{s}^{2}(1-\cos \theta)}\right\} \\
= & \left(g / q_{s}^{2 l+2}\right) Q_{l}\left(1+\left(m^{2} / 2 q_{s}^{2}\right)\right) \tag{2.7}
\end{align*}
$$

This is the first Born approximation to the left-hand cut, and, as in I, we find that to produce a bound state at $s=m^{2}$ we require $g / m^{2}=16.5$, but that then the residue of the output pole is 105 , or very far from a "bootstrap" solution. In Fig. 1 we plot the position of the bound state versus the coupling constant, and in Fig. 2 we show the trajectory on which the particle lies. It will be noted that the trajectory does not rise to large values of $l$, but has a cusp at the threshold. Because the trajectory has a branch point at threshold, the path of the second zero of the real part of the $D$ function (plotted as a dashed line in Fig. 2) can not be identified with the falling trajectory, but is probably reasonably close to it just above threshold. We believe that the contribution of this sort of trajectory to the

Fig. 1. Relativistic bound-state energy squared $s$ versus coupling strength $g$ in units of $m^{2}$. $B_{1}$, $B_{2}$-second Born approximation, primary and secondary. $C_{1}$, $C_{2}$-first Born approximation, primary and secondary.

[^1]
potential is well represented by the $l=0$ "elementary" particle form which we have used (2.7).

However, Luming ${ }^{2}$ has shown that in the nonrelativistic case the solution obtained with such large coupling constants is very far from the correct solution of the Schrödinger equation with a Yukawa potential $g e^{-m r} / r$. (Note that Luming uses $g^{2}$ where we use $g$.)

The main differences between the nonrelativistic and relativistic cases are that the phase-space factor $\rho_{l}(s)$ is changed in the way explained above, and, since there is only one crossed channel, we replace $g$ by $\frac{1}{2} g$. The change of $\rho_{l}$ means that whereas relativistically one can integrate (2.5) to infinity for $l<1$ and still have a Fredholm equation, in the nonrelativistic situation this is true only of $l<\frac{1}{2}$. Otherwise one must use a cutoff; but, as Luming shows, the results depend very little on the magnitude of the cutoff if it is large. We took an upper limit of $200 m^{2}$ in all the calculations reported here, but have verified the insensitivity of the results to the value of this parameter in both the relativistic and non-relativistic cases.

In Fig. 3 we show the plot of bound-state energy versus coupling constant in the nonrelativistic situation and compare it with the exact solution of the Schrödinger equation obtained by Hulthén and Laurikainer. ${ }^{4}$ This agrees with Luming's Fig. 10. It will be observed that there is a considerable discrepancy between the two curves for $s=m^{2}$. However, Luming also shows that there is a great improvement if the second Born approximation to the left-hand cut is used, and we may expect this also to be true for the relativistic case.

## III. THE SECOND BORN APPROXIMATION

Figure 4 shows the Mandelstam representation for the amplitude,

$$
\begin{align*}
A(s, t)= & \frac{g}{m^{2}-t}+\frac{g}{m^{2}-u}+\frac{1}{\pi} \int_{t_{0}}^{\infty} \frac{A_{t}\left(s, t^{\prime}\right)}{\left(t^{\prime}-t\right)} d t^{\prime} \\
& +\frac{1}{\pi} \int_{u_{0}}^{\infty} \frac{A_{u}\left(s, u^{\prime}\right)}{\left(u^{\prime}-u\right)} d u^{\prime} \tag{3.1}
\end{align*}
$$

${ }^{4}$ L. Hulthén and K. V. Laurikainen, Rev. Mod. Phys. 23, 1 (1951).

Fig. 3. Nonrelativistic bound-state energy squared $s$, versus coupling strength $g$ in units of $m^{2} . A_{1}, A_{2}$-solution of the Schrödinger equation, primary and secondary. The other labels correspond to those in Fig. 1.
or ${ }^{5}$

$$
A\left(s, Z_{s}\right)=A_{R}\left(s, z_{s}\right)+A_{L}\left(s, z_{s}\right),
$$

where $A_{R}$ has only the right-hand singularities, $A_{L}$ the left-hand, and $z_{s}$ is the scattering angle in the $s$ channel. We define even and odd signature amplitudes by

$$
\begin{equation*}
A^{ \pm}\left(s, z_{s}\right)=A_{R}\left(s, z_{s}\right) \pm A_{L}\left(s,-z_{s}\right) \tag{3.2}
\end{equation*}
$$

and find, because of the symmetry in $s, t$, and $u$,

$$
\begin{align*}
A^{+}(s, t)= & 2 g /\left(m^{2}-t\right) \\
& +\frac{2}{\pi^{2}} \int^{\infty} \int \rho_{s t}\left(s^{\prime}, t^{\prime}\right)\left[\frac{1}{\left(t^{\prime}-t\right)\left(s^{\prime}-s\right)}\right. \\
& \left.+\frac{1}{\left(t^{\prime}-t\right)\left(s^{\prime}+t^{\prime}-4+s\right)}\right] d s^{\prime} d t^{\prime} \tag{3.3}
\end{align*}
$$

where $\rho_{s t}$ is the double spectral function.

Fig. 4. The Mandelstam representation.
Making the partial-wave projection of (3.3), we find

$$
\begin{align*}
A_{l}+(s)= & \left(g / q_{s}^{2}\right) Q_{l}\left(1+m^{2} / 2 q_{s}{ }^{2}\right) \\
+\frac{2}{\pi^{2}} \int^{\infty} \int \rho_{s t}\left(s^{\prime}, t^{\prime}\right) & {\left[\frac{1}{\left(s^{\prime}-s\right)}+\frac{1}{\left(s^{\prime}+t^{\prime}-4+s\right)}\right] } \\
& \times Q_{l}\left(1+\frac{t^{\prime}}{2 q_{s}{ }^{2}}\right) d s^{\prime} d t^{\prime} . \tag{3.4}
\end{align*}
$$

However, the second term in (3.4) has both left-hand and right-hand cuts in $s$, and to obtain the "potential" from this expression we must subtract the contribution of the right-hand cut $\left(s=s^{\prime}\right)$. Along this cut the imaginary part is

$$
\frac{2}{\pi} \rho_{s t}\left(s, t^{\prime}\right) \frac{Q_{l}\left(1+t^{\prime} / 2 q_{s}{ }^{2}\right)}{2 q_{s}{ }^{2}}
$$

so the contribution to $A_{l}$ is

$$
\frac{2}{\pi^{2}} \int^{\infty} \int^{\rho_{s t}\left(s^{\prime}, t^{\prime}\right)} \frac{Q_{l}\left(1+t^{\prime} / 2 q_{s^{2}}\right)}{\left.2 s^{\prime}-s\right)} \frac{2 s_{s^{\prime}}{ }^{2}}{} d s^{\prime} d t^{\prime}
$$

Thus the final expression for $V_{t}(s)$ is, when we remember the threshold factor,

$$
\begin{align*}
V_{l}(s)=\frac{g}{q_{s}^{2 l+2}} Q_{l}\left(1+\frac{m^{2}}{2 q_{s}^{2}}\right) & +\frac{2}{\pi^{2}} \int^{\infty} \int_{s t}\left(s^{\prime}, t^{\prime}\right) \\
& \times\left\{\frac{1}{\left(s^{\prime}-s\right)}\left[\frac{Q_{l}\left(1+t^{\prime} / 2 q_{s^{2}}^{2}\right)}{2 q_{s}^{2 l+2}}-\frac{Q_{l}\left(1+t^{\prime} / 2 q_{s^{2}}{ }^{2}\right)}{2 q_{s^{\prime}} 2 l+2}\right]+\frac{1}{\left(s^{\prime}+t^{\prime}-4+s\right)} \frac{Q_{l}\left(1+t^{\prime} / 2 q_{s^{2}}\right)}{2 q_{s}^{2 l+2}}\right\} d s^{\prime} d t^{\prime} \tag{3.5}
\end{align*}
$$

For the second Born approximation we must know the elastic part of the double spectral function, which may be obtained by iterating the pole or first Born

[^2]approximation, with elastic unitarity. (See, for example, Ref. 6.)

[^3]The first Born approximation gives

$$
\begin{equation*}
A_{t}{ }^{(1)}(s, t)=\pi g \delta\left(t-m^{2}\right) \tag{3.6}
\end{equation*}
$$

Then

$$
\left.\begin{array}{rl}
\rho_{s t}{ }^{\mathrm{el}}(s, t)= & \frac{1}{\pi q_{s} \sqrt{ } s} \int_{s_{0} t_{0}}^{K=0} \\
+ & \frac{d u^{\prime} d u^{\prime \prime} A_{u}^{(1)}\left(s, u^{\prime \prime} A_{t^{\prime}}^{(1)}\left(s, t^{\prime}\right) A_{u^{(1)}}^{(1)}\left(s, t^{\prime \prime}\right)\right.}{K^{1 / 2}\left(q_{s}^{2}, t, t^{\prime}, t^{\prime \prime}\right)}  \tag{3.7}\\
K^{1 / 2}\left(q_{s}^{2}, t, u^{\prime}, u^{\prime \prime}\right)
\end{array}\right], ~ l
$$

where

$$
\begin{align*}
& K\left(q_{s}^{2}, t, t^{\prime}, t^{\prime \prime}\right) \\
& \quad=\left[t^{2}+t^{\prime 2}+t^{\prime \prime 2}-2\left(t t^{\prime}+t^{\prime} t^{\prime \prime}+t^{\prime \prime} t\right)-\left(t t^{\prime} t^{\prime \prime} / q_{s}^{2}\right)\right] \tag{3.8}
\end{align*}
$$

Combining (3.6), (3.7), and (3.8) gives

$$
\begin{equation*}
\rho_{s t}^{\mathrm{el}}(s, t)=\left(2 \pi g^{2} / q_{s} \sqrt{ } s\right)\left(t^{2}-4 t m^{2}-t m^{4} / q_{s}^{2}\right)^{-1 / 2} \tag{3.9}
\end{equation*}
$$

with a boundary at

$$
\begin{equation*}
s=[4 /(t-4)]+4 \tag{3.10}
\end{equation*}
$$

We use (3.9) substituted in (3.5) to give the "potential." The corresponding nonrelativistic expressions are

$$
\begin{gather*}
V_{l}(s)=\frac{g}{2 q_{s}^{2 l+2}} Q_{l}\left(1+\frac{m}{2 q_{s}^{2}}\right)+\frac{2}{\pi 2} \int^{\infty} \int^{\infty} \rho_{s t}\left(s^{\prime}, t^{\prime}\right) \frac{1}{s^{\prime}-s} \\
\times\left[\frac{Q_{l}\left(1+t^{\prime} / 2 q_{s}^{2}\right)}{2 q_{s}^{2 l+2}}-\frac{Q_{l}\left(1+t^{\prime} / 2 q_{s^{2}}{ }^{2}\right)}{2 q_{s^{\prime}}{ }^{2}}\right] \tag{3.11}
\end{gather*}
$$

with ${ }^{7}$

$$
\begin{equation*}
\rho_{s t}{ }^{\mathrm{el}}(s, t)=\left(\pi g^{2} / 2 q_{s}\right)\left(t^{2}-4 t m^{2}-t m^{4} / q_{s}^{2}\right)^{-1 / 2} \tag{3.12}
\end{equation*}
$$

reflecting the absence of the third double-spectral function, and the altered unitarity condition.

Since $\rho_{s t}{ }^{\text {el }}$ depends upon $g^{2}$ we can expect it to become more important as $g$ increases. Figures 1 and 3 show the results of solving the $N / D$ equations with these "potentials." Again in Fig. 3 we have reasonable agreement with Luming's results.
In the relativistic case a bound state is produced at $m^{2}$ with $g=4.5 m^{2}$, but $g^{\prime}=56 m^{2}$, so we are no nearer to a bootstrap solution. The trajectories concerned are shown in Fig. 5. It still proves impossible to produce a secondary trajectory passing through $m^{2}$ at $l=0$ however large $g$ may be, so the chances of obtaining a bootstrap solution in this way are negligible.

However, one may object to the use of this form of the double-spectral function from the point of view of continuation in angular momentum. ${ }^{8}$ We know that the contribution of a Regge pole to the amplitude may

[^4]

Fig. 5. Trajectories for $g=4.5 m^{2}$, relativistic second Born approximation.
be written
$A(s, t)=-\frac{\pi[2 \alpha(t)+1]}{2} \frac{\sin (\pi \alpha(t))}{\sin }(t)\left(-q_{t}{ }^{2}\right)^{\alpha(t)} P_{\alpha(t)}\left(1+\frac{s}{2 q_{t}^{2}}\right)$,
and our fixed $l=0$ pole comes from putting

$$
\alpha(t) \underset{t \rightarrow m 2}{\rightarrow} \alpha^{\prime}\left(m^{2}\right)\left(t-m^{2}\right)
$$

and then using this for all $t$ with

$$
g=\frac{1}{2} \gamma\left(m^{2}\right) / \alpha^{\prime}\left(m^{2}\right)
$$

But (3.13) shows that the use of (3.6) for $A_{t}{ }^{(1)}(s, t)$ is not justified for large $s$, since we obtain

$$
A_{t}{ }^{(1)}(s, t) \underset{s \rightarrow \infty}{ } \propto s^{\alpha(t)}
$$

Substituting in (3.7) would give us
$\rho_{s t^{e 1}}(s, t) \underset{s \rightarrow \infty}{ } \iint d t^{\prime} d t^{\prime \prime} s^{\alpha\left(t^{\prime}\right)+\alpha\left(t^{\prime \prime}\right)-1} \times\left(\right.$ terms in $\left.t, t^{\prime}, t^{\prime \prime}\right)$.
Figure 5 shows that there is a region of $t$ from $m^{2}$ to about $10 m^{2}$ for which $\operatorname{Re} \alpha(t)>0$, and the integral in (3.11) is not well approximated by our use of $\alpha=0$ in this region, and it will even diverge if there is a region where $\alpha(t)>\frac{1}{2}$. But we also know that the asymptotic behavior given by the first Mandelstam iteration is incorrect, and in fact we should have

$$
\rho_{s t}(s, t) \underset{s \rightarrow \infty}{\propto} s^{\alpha(t)} .
$$

In other words, the elastic double-spectral function does not represent the behavior of the total doublespectral function for large $s$, and in fact (3.11) should converge providing that $\operatorname{Re} \alpha(t)<0$.

In the following Section we present a method of increasing the convergence of the integral (3.11) whereby only the near (small $s$ ) region of the double spectral function is important, and the asymptotic region, where the elastic double-spectral function is not reliable, has little influence.

## IV. A SUBTRACTION DETERMINED BY REGGE ASYMPTOTIC BEHAVIOR

In the previous work ${ }^{1}$ we tried to represent the effect of the double-spectral functions by including the force from the $S$-wave part of the elastic discontinuity in the crossed channels. The double-spectral function, of course, gives the sum of all the partial waves, but it is still convenient to subtract the $S$-wave part and then add it back in the same manner as in I. We know that the Regge asymptotic behavior of the double-spectral function determines the number of subtractions needed to make integrals like (3.3) converge; and in our case, where $\alpha(t)<1$, we need make only one subtraction of the $S$-wave discontinuity.

The total discontinuity in the $t$ channel is

$$
\begin{equation*}
A_{t}(s, t)=\frac{1}{\pi} \int d s^{\prime} \rho_{s t}\left(s^{\prime}, t\right)\left[\frac{1}{\left(s^{\prime}-s\right)}+\frac{1}{\left(s^{\prime}+t-4+s\right)}\right] \tag{4.1}
\end{equation*}
$$

$$
\begin{align*}
& A_{l}(s)=\frac{g}{q_{s}{ }^{2}} Q_{l}\left(1+\frac{m^{2}}{2 q_{s}{ }^{2}}\right)+\frac{2}{\pi} \int A_{t}{ }^{l_{t}=0}\left(t^{\prime}\right) Q_{l}\left(1+\frac{t^{\prime}}{2 q_{s}{ }^{2}}\right) \frac{d t^{\prime}}{2 q_{s}{ }^{2}} \\
&+\frac{2}{\pi^{2}} \iint \rho_{s t}\left(s^{\prime}, t^{\prime}\right)\left[\frac{1}{\left(s^{\prime}-s\right)}+\frac{1}{\left(s^{\prime}+t^{\prime}-4+s\right)}-\frac{1}{q_{t^{\prime}}{ }^{2}} Q_{0}\left(1+\frac{s^{\prime}}{2 q_{t^{2}}{ }^{2}}\right)\right] \frac{Q_{l}\left(1+t^{\prime} / 2 q_{s}{ }^{2}\right)}{2 q_{s}{ }^{2}} d s^{\prime} d t^{\prime} \tag{4.5}
\end{align*}
$$

Finally, removing the right-hand cut in analogy with Sec. III, we have

$$
\begin{align*}
V_{l}(s)=\frac{g}{q_{s}^{2 l+2}} Q_{l}\left(1+\frac{m^{2}}{2 q_{s}{ }^{2}}\right)+ & \frac{2}{\pi} \int A_{t}{ }^{l=0}\left(t^{\prime}\right) \frac{Q_{l}\left(1+t^{\prime} / 2 q_{s^{2}}\right)}{2 q_{s}^{2 l+2}} d t^{\prime} \\
& +\frac{2}{\pi^{2}} \iint \rho_{s t}\left(s^{\prime}, t^{\prime}\right)\left\{\left[\frac{1}{\left(s^{\prime}-s\right)}+\frac{1}{\left(s^{\prime}+t^{\prime}-4+s\right)}-\frac{1}{q_{t^{\prime}}{ }^{2}} Q_{0}\left(1+\frac{s^{\prime}}{2 q_{t^{\prime}}{ }^{2}}\right)\right]\right. \\
& \left.\quad \times \frac{Q_{l}\left(1+t^{\prime} / 2 q_{s^{2}}{ }^{2}\right)}{2 q_{s}^{2 l+2}} \frac{1}{\left(s^{\prime}-s\right)} \cdot \frac{Q_{l}\left(1+t^{\prime} / 2 q_{s^{\prime}}{ }^{2}\right)}{2 q_{s^{2}}{ }^{2 l+2}}\right\} d s^{\prime} d t^{\prime} \tag{4.6}
\end{align*}
$$

We can immediately see that the convergence of the double integral has been improved, since

$$
q_{t^{\prime \prime}}{ }^{-2} Q_{0}\left(1+s^{\prime} / 2 q_{t^{\prime}}\right) \underset{s^{\prime} \rightarrow \infty}{\rightarrow}\left(2 / s^{\prime}\right)
$$

which cancels with the first term in the expansion of $\left[1 /\left(s^{\prime}-s\right)+1 /\left(s^{\prime}+t^{\prime}-4+s\right)\right]$ in powers of $(1 / s)^{\prime}$, leading to

$$
\frac{2}{\pi^{2}} \iint \rho_{s t}\left(s^{\prime}, t^{\prime}\right) \times\left(\text { terms of order } \frac{1}{s^{\prime 2}}\right) d s^{\prime} d t^{\prime}
$$

which will converge if $\alpha(t)<1$. Figure 5 shows that in fact $\alpha$ is always less than 1 , and so we have removed the difficulties described in the previous section, though at the expense of some computational complexity. The second term in (4.6) is to be evaluated by the same sort
and

$$
\begin{equation*}
A_{t^{\prime}=0}^{\prime=0}(t)=\frac{2}{\pi} \int d s^{\prime} \rho_{s t}\left(s^{\prime}, t\right) \frac{Q_{0}\left(1+s^{\prime} / 2 q_{t^{2}}\right)}{2 q_{t^{2}}^{2}} d s^{\prime} \tag{4.2}
\end{equation*}
$$

Thus we may write

$$
\begin{align*}
& \begin{array}{l}
A_{t}(s, t)=A_{t^{\prime}=0}^{l_{t=0}}(t)+\frac{1}{\pi} \int \rho_{s t}\left(s^{\prime}, t\right)
\end{array} \frac{1}{\left(s^{\prime}-s\right)}+\frac{1}{\left(s^{\prime}+t-4+s\right)} \\
&  \tag{4.3}\\
& \text { And since }
\end{align*}
$$

$$
\begin{align*}
& A_{l}(s)=\frac{g}{q_{s}^{2}} Q_{l}\left(1+\frac{m^{2}}{2 q_{s}^{2}}\right) \\
& \quad+\frac{2}{\pi} \int A_{t}\left(s, t^{\prime}\right) Q_{l}\left(1+\frac{t^{\prime}}{2 q_{s}^{2}}\right) \frac{d t^{\prime}}{2 q_{s}^{2}{ }^{2}} \tag{4.4}
\end{align*}
$$

we have
of cycling procedure we described in I, whereby we impose equality upon the discontinuities in the $s$ and $t$ channels.

As in the previous section we shall make the approximation of replacing $\rho_{s t}$ by $\rho_{s t}{ }^{\text {el }}$. Since only the low-s part is now important, this should be a good approximation.

## V. THE CONFLICT WITH UNITARITY

On evaluating the double integral in (4.6) we find that its contribution to $V_{t}$ is negative, indicating that the $S$-wave ( $t$-channel) part which we have removed is greater than the contribution of the double-spectral function, if we subtract from the double-spectral function's contribution that part which gives rise to the right-hand cut (in the $s$ channel). Of course the $S$-wave part is smaller than the total contribution of the doublespectral function (since the individual partial waves are
positive) and it is only because of the removal of the right-hand-cut part that the result is negative. The partial-wave series does not converge along the righthand cut.

Since $\rho_{s t}{ }^{\text {el }}$ depends on $g^{2}$, this negative contribution rapidly increases with the coupling. If we could achieve self-consistency, the second term in (4.6) would outweigh the part subtracted, so that total potential would be positive. But this term is limited by unitarity in the $t$ channel, whereas the double-spectral function is calculated with the use of unitarity in the $s$ channel only.
When we solve the equations we find that, except for small values of $g$, the negative contribution of the double-spectral function dominates, producing a repulsive potential. Thus except for very small $g$ the elastic double-spectral function, obtained by iterating the $t$-channel poles with elastic unitarity in the $s$ channel, conflicts with the requirement of unitarity in
the $t$ channel. A unitary crossing-symmetric $S$ matrix can not be obtained.
The values of $g$ which do not produce this conflict are too small for a bound state to be formed at $s=m^{2}$, so it is not possible to make the $S$ matrix crossing symmetric even with regard to the positions of the poles as we had supposed in I.

## ACKNOWLEDGMENTS

I would like to thank Professor G. F. Chew for innumerable discussions and suggestions throughout the course of this work. Thanks are also due to D. C. Teplitz and V. L. Teplitz for the use of their computer program. The hospitality of the Lawrence Radiation Laboratory is gratefully acknowledged. The work was performed while I was the holder of a D.S.I.R. research fellowship.

# Two-Body Effective-Mass Spectra in the Products of the Reaction $\gamma+p \rightarrow p+\pi^{+}+\pi^{-}$and the $\sigma$ Resonance

#### Abstract

By means of spark chambers and counters we measured the ( $\pi^{+}, \pi^{-}$) and ( $\pi^{ \pm}, p$ ) invariant-mass spectra obtained from the products of the reaction $\gamma+p \rightarrow p+\pi^{+}+\pi^{-}$. They are in disagreement with the CutkoskyZachariasen model which takes into account the effect of the $\frac{3}{2}, \frac{3}{2}$ nucleon isobar. To fit our data we introduce a $\pi-\pi$ final-state enhancement factor with resonant behavior. The resonance energy is around 380 MeV .

## 1. INTRODUCTION

USING the $1100-\mathrm{MeV}$ bremsstrahlung beam of the Frascati electron synchrotron we studied the process

$$
\begin{equation*}
\gamma+p \rightarrow p+\pi^{+}+\pi^{-} \tag{1}
\end{equation*}
$$

Our aim was to measure the spectra of the invariant mass of the pion-pion system $m_{\pi \pi}$ and pion-nucleon system $m_{p \pi}$. This was obtained by determining the flight directions of the three final particles together with the proton momentum by means of a system of spark chambers. The observed protons are those emitted at laboratory angles $\theta_{p}$ around $35^{\circ}$. Our ex-

[^5]perimental method does not allow us to distinguish the charges of the two pions.

In our kinematical configuration the $(\pi, p)$ invariant mass lies within the interval $1100-1400 \mathrm{MeV}$, and therefore the contribution of the $\frac{3}{2}, \frac{3}{2}$ nucleon isobar should be dominant. This contribution has been calculated by Cutkosky and Zachariasen ${ }^{1}$ (abbreviated CZ ) making use of the static model. The results of our experiment are in strong disagreement with the $C Z$ predictions, both in the absolute values of the cross sections and in the shape of the $m_{\pi \pi}$ spectra. If we assume that the recoil corrections to the CZ model do not change its predictions qualitatively, our experimental results may be taken as an indication of the presence of other important terms besides those due to the $\frac{3}{2}, \frac{3}{2}$ isobar. Actually a noteworthy contribution of the pion-pion interaction in the $T=J=1$ state ( $\rho$ meson) has been brought to light in reaction (1) by McLeod, Richert, and Silverman, ${ }^{2}$ for values of
